1. What is an intercostal catheter?

An intercostal catheter (ICC) or chest tube is put in between the ribs into the space located between the lung and the chest wall (pleural space). The chest tube drains the air or fluid from the pleural space.

Your medical condition will determine the position of the chest tube eg, in the armpit, in the back of the chest or in the front of the chest below the collarbone.

You will have the following procedure:

The area where the chest tube goes is numbed with an injection of local anaesthetic. A small cut is made into the skin and tissue. A tunnel is made through the tissue so the chest tube can be placed into the pleural space.

The chest tube is joined to a drainage tube and bottle. Stitches may be put into the skin to hold the chest tube in place. A dressing is put on to cover the area.

The tube may be painful, especially when you move so you may require pain relief medication.

After the tube is put in, a chest X-ray is taken to check that the tube is in the correct position.

What happens while the chest tube is in?

The chest tube is connected to a drainage bottle that has some water in it.

If the chest tube is inserted because there is air in the pleural space, you will see the water in the drainage tube moving and you will see bubbles in the water in the bottle. This is normal. This shows that the tube is working and that air is draining from the chest.

If the chest tube is inserted because there is fluid in the pleural space, you will see fluid drain via the tube into the drainage bottle. Sometimes the drainage bottle is connected to a suction valve on the wall. This helps suck out the air or fluid.

Please tell the staff if you have any pain or shortness of breath ('feeling puffed').

When is the chest tube (ICC) removed?

The tube is removed when air has stopped draining from the chest or when the amount of fluid draining from the chest has reduced or stopped.

How is the chest tube (ICC) removed?

Your doctor or nurse will tell you how to breathe while the tube is pulled out of the pleural space. Some stitches may be needed to close the wound.

A chest X-ray is done after the tube has been removed. The doctor will tell you when the stitches are to come out and when to take the dressing off.

The wound and dressing are to be kept dry for 2 days.

Does a chest tube (ICC) always resolve the problem?

The chest tube may block and may need to be replaced. If the air leak from the lung continues or the fluid remains, additional procedures may be required. Your doctor will talk to you about what can be done if this happens.

2. My anaesthetic

This procedure will require an anaesthetic.

See Local Anaesthetic and Sedation for Your Procedure information sheet for information about the anaesthetic and the risks involved. If you have any concerns, discuss these with your doctor.

If you have not been given an information sheet, please ask for one.

3. What are the risks of this specific procedure?

In recommending this procedure your doctor has balanced the benefits and risks of the procedure against the benefits and risks of not proceeding. Your doctor believes there is a net benefit to you going ahead.

There are risks and complications with this procedure. They include but are not limited to the following.

Common risks and complications (more than5%) include

- The chest tube may become kinked or blocked. Sometimes it needs to be repositioned or replaced.
- Increased risk in obese people of wound infection, chest infection, heart and lung complications and thrombosis.

Uncommon risks and complications (1- 5%) include

- Infection. This may need treatment with antibiotics.
- Bleeding from damaged blood vessels in between the ribs.
- Irritation of the nerves between the ribs, which may cause pain or numbness in the chest.
- Congestion may occur in the lung after air or fluid is removed. You may feel short of breath soon after the chest tube is put in.

Rare risks and complications (less than1%) include

- The chest tube may damage the lung or damage other parts of the body. (For example the heart, the food pipe, the muscle under the lungs or the liver or spleen).
- Emergency surgery due to complications with the procedure.
- Death as a result of this procedure is rare.
