

How does fluoride work?

Water fluoridation combats tooth decay in three ways.

Bacteria in the mouth make acids that cause tooth decay.

Fluoride stops the acids attacking the teeth.

Without fluoride – bacteria containing acid breaks down tooth enamel and causes tooth decay.

Drinking fluoridated water replaces lost minerals and repairs damaged tooth enamel. This continual replacement stops the progression of tooth decay.

Water fluoridation

The benefits of water fluoridation

- Our teeth need the protection of fluoride throughout life to avoid the pain and costs of tooth decay.
- Children benefit as soon as their teeth are formed – giving the best chance of having healthy teeth for life.
- Teenagers benefit as they are at higher risk of developing tooth decay.
- Young adults benefit as they can spend less time and money on expensive dental treatment.
- Middle aged people can enjoy a healthier more comfortable lifestyle by avoiding the pain and costs of dental treatment.
- Elderly people are now keeping their teeth longer and will benefit from being well-protected against tooth decay.

No matter what age everyone benefits from fluoride

Water fluoridation in Queensland

Some parts of Queensland have been fluoridated for decades. For example, Townsville has been fluoridated for more than 40 years.

In recent years the number of Queenslanders who have access to the benefits of water fluoridation has dramatically increased. For example, the majority of south east Queensland has been fluoridated for four years.

Other Australian States and Territories have been fluoridated for 30–50 years.

Safety of water fluoridation

Water fluoridation gives extra protection against tooth decay but a healthy diet, regular brushing and flossing and regular dental check-ups are all essential for good oral health.

The fluoridation of public water supplies has been practised around the world for more than 60 years, it is acknowledged as one of the 10 greatest public health achievements for the 20th century.

Numerous studies and reviews have confirmed the safety and effectiveness of water fluoridation in reducing dental decay for the whole population.

Common fluoride myths

Myth: *Water fluoridation is bad for babies*

Fact: Water fluoridation has been endorsed by the World Health Organization, Australian Medical Association and American Academy of Pediatrics, and poses no known health risks for babies and young children.

Myth: *Fluoride causes cancer*

Fact: Cancer rates in the rest of Australia (mostly fluoridated for decades) are no higher than in Queensland (largely non-fluoridated until 2008).

Myth: *Fluoride causes allergies*

Fact: Fluoride is found naturally in most foods and water. No credible research has linked water fluoridation to allergies, hypersensitivity or other immunological effects.

Myth: *Water fluoridation is banned in Europe*

Fact: No country has banned water fluoridation.

Fact: Many countries use salt fluoridation as an alternative.

Myth: *Water fluoridation is mass medication*

Fact: The Department of Health does not consider the addition of fluoride to drinking water to be ‘mass medication’, but simply adjusting the level of a substance already found naturally in the water to provide a substantial public health benefit.

Water fluoridation — better health for all Queenslanders
